## ABSTRACT

011 Persistent memory is essential for long-lived LLM agents, yet existing benchmarks  
012 primarily evaluate retrieval from available context rather than memory cur-  
013 ration: the ability to decide what to store, update, delete, and consolidate over  
014 time. We introduce MEMORYBENCH, a diagnostic benchmark for evaluating end-  
015 to-end persistent memory systems when prior sessions are no longer accessible.<sup>1</sup>

016 MEMORYBENCH comprises 71 tests across 7 failure categories spanning 20 multi-  
017 session user profiles. Each category corresponds to a distinct memory operation:  
018 handling contradictions, expiring stale information, filtering noise, inferring im-  
019 plicit preferences, consolidating related facts, and synthesizing across sessions.  
020 This enables fine-grained diagnosis of memory system behavior. The benchmark  
021 includes structured ground-truth annotations and a controlled evaluation protocol  
022 that standardizes the underlying LLM, embeddings, and conversations to isolate  
023 memory pipeline differences.

024 We demonstrate that MEMORYBENCH reveals complementary strengths and blind  
025 spots across representative memory architectures, and we release it as an open, ex-  
026 tensible framework to support systematic evaluation and development of persistent  
027 memory systems for LLM agents.

## 1 INTRODUCTION

029 Persistent memory is essential for long-lived LLM agents. Personal assistants, coding copilots,  
030 research collaborators, and enterprise agents must remember information across sessions to provide  
031 coherent and personalized interaction. Over time, users change roles, relocate, revise plans, and  
032 express evolving preferences. Memory systems must therefore decide not only what to remember,  
033 but also what to update, consolidate, or ignore as conversations unfold.

034 Two dominant paradigms have emerged. In **agent-managed memory**, the conversational LLM  
035 directly controls memory operations such as adding, updating, or deleting entries (Park et al., 2023;  
036 Packer et al., 2023). In **external memory services**, memory management is handled by automated  
037 extraction pipelines that operate alongside the conversational model. Both paradigms are actively  
038 deployed, yet empirical comparison under controlled conditions remains limited.

039 Existing benchmarks primarily evaluate memory *retrieval*—whether models can access relevant in-  
040 formation from long contexts (Liu et al., 2024; Bai et al., 2024) or multi-session transcripts (Maha-  
041 rana et al., 2024). These settings assume that past information remains available at inference time.  
042 In contrast, deployed memory systems operate under context loss: prior sessions are not directly  
043 accessible, and behavior depends entirely on what the memory pipeline previously stored and how  
044 effectively it can retrieve it. Evaluating such systems requires moving beyond retrieval accuracy  
045 toward structured analysis of persistent memory behavior.

046 We introduce MEMORYBENCH, a diagnostic benchmark for end-to-end persistent memory systems.  
047 The benchmark comprises 71 tests across 7 failure categories spanning 20 multi-session user pro-  
048 files. Each category corresponds to a distinct memory operation—handling contradictions, ex-  
049 piring stale information, filtering noise, inferring implicit preferences, consolidating related facts, and

054

055

Table 1: MEMORYBENCH diagnostic categories (71 tests across 20 profiles).

056

057

Category	N	Example
Contradiction Update	18	“Where am I based now?” (NYC → SF)
Temporal Relevance	10	“Am I still on-call this week?”
Noise Resistance	9	“Do you remember the coffee incident?”
Implicit Preference	10	“How should you explain things to me?”
Simple Recall	8	“What framework am I using?”
Consolidation	8	“How has my model’s performance evolved?”
Cross-Session Synthesis	8	“What’s my overall learning journey?”
<b>Total</b>	<b>71</b>	

064

065

066

067

synthesizing across sessions. By organizing evaluation around these categories, MEMORYBENCH reveals not only overall accuracy but also *why* systems fail.

068

069

070

071

072

073

074

Importantly, MEMORYBENCH evaluates complete memory pipelines—including storage, indexing, and retrieval—under controlled conditions. We standardize the underlying LLM, embeddings, and conversations to isolate differences in memory management strategies. This design enables principled comparison between agent-managed and external memory paradigms while reflecting the operational realities of deployed systems.

075

076

077

078

079

080

**Contributions.** (1) We introduce MEMORYBENCH, a structured diagnostic benchmark for persistent memory systems with multi-session profiles and category-level evaluation. (2) We provide a controlled comparison of representative agent-managed and external memory approaches, revealing complementary strengths across memory operations. (3) We release MEMORYBENCH as an extensible framework to support systematic evaluation and development of memory systems for long-lived LLM agents.

081

082

## 2 MEMORYBENCH

083

MEMORYBENCH is designed around three principles.

084

**(1) Multi-session realism.** Persistent memory failures arise over time rather than within a single conversation. Each profile spans five sessions reflecting natural evolution (e.g., job transitions, relocations, shifting priorities, evolving preferences).

085

**(2) Structured ground truth.** Each profile includes explicit annotations specifying what information should be stored, what supersedes earlier facts, and what constitutes irrelevant noise. Session 5 contains evaluation queries aligned with these annotations.

086

**(3) Diagnostic categorization.** Tests are grouped into seven failure categories corresponding to distinct memory operations, enabling fine-grained analysis of system behavior beyond aggregate accuracy.

087

Profiles span ten professional domains (e.g., software engineering, data science, game development, clinical research). Each contains five multi-turn sessions averaging 3 to 5 turns. Sessions 1 through 4 embed memory challenges within natural dialogue. Session 5 contains evaluation queries assessed against gold references.

088

### 2.1 EVALUATION PROTOCOL

089

090

091

For each profile, we initialize an empty memory store and sequentially process Sessions 1 through 4 using the memory system under study. At evaluation time (Session 5), prior conversations are not available; systems must rely exclusively on persisted memory. For each query, the system retrieves the top-5 memories via semantic similarity and generates a response.

092

093

094

All systems use the same conversational model (GPT-4o-mini), embedding model (text-embedding-3-small), and conversation transcripts to isolate differences in memory management strategies. Responses are scored as {correct, partially correct, incorrect}.

108

109

Table 2: Overall accuracy across 71 memory tests (20 profiles).

110

111

System	Strict	w/ Partial	Correct	Partial	Incorrect
Agent-Driven	62.0%	<b>75.4%</b>	44	19	8
LangMem	62.0%	71.1%	44	13	14
Mem0	45.1%	59.9%	32	21	17

112

113

114

115

## 2.2 JUDGE RELIABILITY

116

117

To assess scoring reliability, two annotators independently reviewed all 71 evaluation cases (query, system answer, gold reference) and assigned labels using the same three-way scheme. Agreement with the automated judge was 97.2% (69/71). The two disagreements involved borderline distinctions between partially correct and correct responses and were resolved through discussion. This analysis suggests that scoring noise does not materially affect aggregate comparisons.

118

119

120

121

122

123

## 3 SYSTEMS UNDER STUDY

124

125

We evaluate three representative persistent memory systems under controlled conditions.

126

127

128

129

130

**Agent-Driven.** A conversational design in which a single LLM call per turn produces both the user response and memory operations (add, update, delete). Memory decisions are generated directly from conversational context. When the store exceeds 20 entries, a consolidation step merges related memories.

131

132

**Mem0.** An LLM-based extraction pipeline that processes completed conversations to extract candidate memories, followed by deduplication against existing entries.

133

134

135

**LangMem.** A semantic memory manager that tracks memory objects across invocations, providing existing memories during subsequent extraction to support updates when contradictions arise.

136

137

A no-memory baseline (current session only) achieves 11% strict accuracy, confirming that persistent memory materially improves performance.

138

139

140

All systems employ top-5 semantic retrieval at evaluation time. In deployed agents, utility depends on both correct storage and effective retrievability; MEMORYBENCH therefore evaluates complete memory pipelines rather than isolated storage decisions.

141

142

143

## 4 RESULTS

144

145

146

147

148

149

150

Our goal is not to establish a leaderboard or declare one memory paradigm superior. Rather, we use representative systems to demonstrate how MEMORYBENCH’s taxonomy reveals structured differences in persistent memory behavior. Results are therefore illustrative rather than definitive. Absolute performance may vary with different prompts, embedding models, retrieval configurations, or implementation details. Our controlled setup (same LLM, embeddings, and conversations) aims to isolate memory management strategies, but the primary contribution of this work is the diagnostic framework itself.

151

152

153

Agent-Driven and LangMem achieve identical strict accuracy (62.0%), while Mem0 performs lower (45.1%). Although aggregate metrics appear similar between the top two systems, category-level analysis reveals meaningful differences (Figure 1).

154

155

156

157

**Contradiction update and temporal relevance.** Agent-Driven performs best on contradiction updates (83.3%) and temporal relevance (80.0%), outperforming both external systems. These categories require recognizing superseded or expired information during conversation.

158

159

160

161

**Cross-session synthesis.** LangMem achieves the highest performance on cross-session synthesis (50.0% vs. 12.5% for Agent-Driven). These tests require integrating information distributed across multiple sessions. Error analysis suggests that synthesizing multi-aspect information remains challenging for all systems.

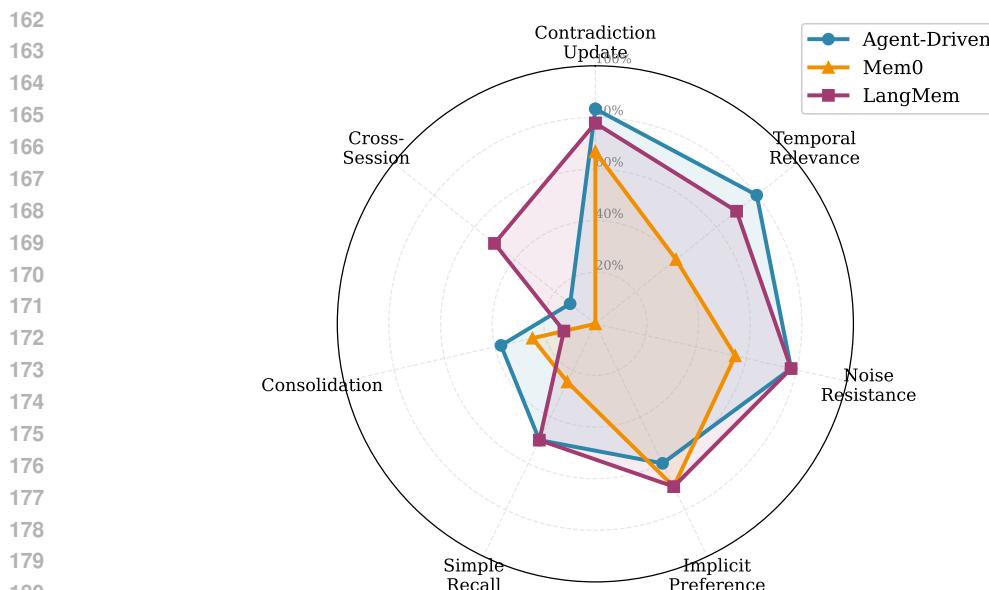

Figure 1: Per-category strict accuracy across three systems. Performance profiles differ substantially across memory operations.

**Implicit preferences and noise resistance.** External systems match or exceed Agent-Driven on implicit preference extraction (70.0% vs. 60.0%). Noise resistance results are comparable between Agent-Driven and LangMem (77.8%), with Mem0 performing lower.

**Prompt sensitivity.** Improving the Agent-Driven extraction prompt increases strict accuracy from 46.5% to 62.0% (+15.5pp), without architectural changes. This suggests that memory extraction quality substantially influences persistent memory performance.

## 5 DISCUSSION

MEMORYBENCH demonstrates that persistent memory systems exhibit complementary strengths across memory operations. Agent-managed systems benefit from conversational context when handling temporal updates and contradictions, while structured extraction pipelines can better aggregate information across sessions.

**Operational trade-offs.** Agent-Driven maintains a smaller memory store (8.8 entries per profile) compared to Mem0 (23.0 entries), which may reduce retrieval noise but risks missing long-range synthesis opportunities. External systems leverage full-store access during extraction but may retain redundant or outdated entries if updates are imperfect.

**Extraction as a bottleneck.** The substantial improvement from prompt refinement suggests that extraction quality, rather than paradigm choice alone, is a central determinant of memory performance.

**Limitations.** The benchmark includes 71 tests and serves as an initial diagnostic suite rather than a comprehensive evaluation standard. Profiles are synthetic and may not capture the full diversity of real-world interactions. We evaluate a single LLM and embedding model, and results may vary across model families. Experiments were conducted as single trials due to cost constraints.

**Retrieval-curation coupling.** MEMORYBENCH evaluates end-to-end persistent memory systems. Storage correctness and retrievability are operationally intertwined: a memory that cannot be retrieved is functionally equivalent to a missing memory. While categories align with specific memory

216 operations, results reflect complete pipeline behavior. Future work may further disentangle storage  
 217 and retrieval via oracle evaluation or explicit recall metrics.  
 218

219 **Benchmark purpose.** The system comparison presented here is intended to illustrate the diagnostic  
 220 value of MEMORYBENCH, not to provide a definitive ranking of memory architectures. Performance  
 221 is sensitive to configuration choices, including prompt design, retrieval parameters, embedding  
 222 models, and implementation details. Different configurations could shift aggregate scores. The  
 223 central contribution of this work is the taxonomy and evaluation protocol, which enable structured  
 224 analysis of such differences.

## 226 6 CONCLUSION

228 We presented MEMORYBENCH, a diagnostic benchmark for evaluating persistent memory systems  
 229 in long-lived LLM agents. By organizing evaluation around seven memory operations and com-  
 230 paring representative paradigms under controlled conditions, the benchmark reveals structured dif-  
 231 ferences that aggregate accuracy obscures. MEMORYBENCH provides an extensible framework for  
 232 analyzing and improving memory system behavior in deployed LLM agents.
